

Adjusted association of aneurysm morphometry with aSAH severity

Proportional-odds ordinal regression, multiple imputation (m = 20); one index per model, OR per 1 SD.

Each estimate is a separate single-index model adjusted for age, sex, smoking, hypertension, diabetes, statin use, and aneurysm circulation. Marker size ∝ precision. Bold, FDR < 0.05. Complete-case estimates in Table 2. FDR, Benjamini–Hochberg false-discovery rate; SD, standard deviation.
